#### UV-Vis (Absorption) Spectrometry (Chapters 13, 14)

#### Beer's Law:

$$A = \varepsilon bc = -\log T = -\log \frac{I}{I_0} = \log \frac{I_0}{I}$$

Absorbance is additive

$$A_{\text{total}} = A_1 + A_2 \dots$$
$$= \varepsilon_1 b c_1 + \varepsilon_2 b c_2 \dots$$

in a 2 component mixture

$$A_{\lambda 1} = \varepsilon_{1,\lambda 1} \cdot b \cdot c_1 + \varepsilon_{2,\lambda 1} \cdot b \cdot c_2$$
$$A_{\lambda 2} = \varepsilon_{1,\lambda 2} \cdot b \cdot c_1 + \varepsilon_{2,\lambda 2} \cdot b \cdot c_2$$

## Limitations of Beer's Law (pp 303-311):

(1) Chemical effects - analyte associates, dissociates or reacts to give molecule with different  $\varepsilon$ 

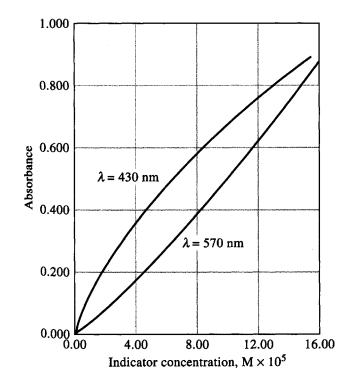

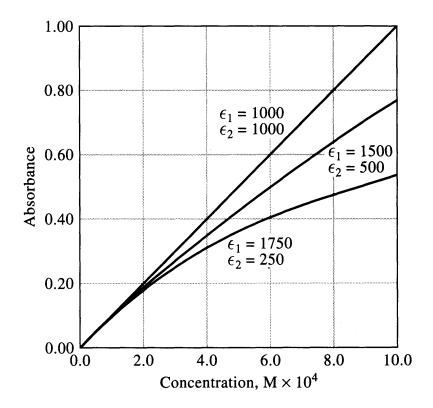

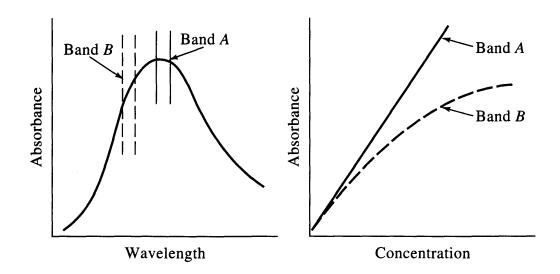

Fig 13-3

(2) Physical effects - stray light, polychromatic radiation or noise

$$\begin{split} \mathbf{A}_{\lambda_1} &= -\log \mathbf{T}_{\lambda_1} = \boldsymbol{\epsilon}_{\lambda_1} bc \\ &= \log \left( \frac{\mathbf{I}_0}{\mathbf{I}} \right)_{\lambda_1} \\ \mathbf{I}_{\lambda_1} &= \mathbf{I}_{0 \lambda_1} 10^{-\boldsymbol{\epsilon}_{\lambda_1} bc} \\ \mathbf{I}_{\lambda_2} &= \mathbf{I}_{0 \lambda_2} 10^{-\boldsymbol{\epsilon}_{\lambda_2} bc} \\ \mathbf{A}_{\overline{\lambda}} &= \left( \frac{\mathbf{I}_{0 \lambda_1} + \mathbf{I}_{0 \lambda_2}}{\mathbf{I}_{\lambda_1} + \mathbf{I}_{\lambda_2}} \right) \\ &= \left( \frac{\mathbf{I}_{0 \lambda_1} + \mathbf{I}_{0 \lambda_2}}{\mathbf{I}_{0 \lambda_1} 10^{-\boldsymbol{\epsilon}_{\lambda_1} bc} + \mathbf{I}_{0 \lambda_2} 10^{-\boldsymbol{\epsilon}_{\lambda_2} bc}} \right) \\ \mathbf{A}_{\overline{\lambda}} &= \log \left( \mathbf{I}_{0 \lambda_1} + \mathbf{I}_{0 \lambda_2} \right) - \log \left( \mathbf{I}_{0 \lambda_1} 10^{-\boldsymbol{\epsilon}_{\lambda_1} bc} + \mathbf{I}_{0 \lambda_2} 10^{-\boldsymbol{\epsilon}_{\lambda_2} bc} \right) \end{split}$$

# → non-linear calibration curve (Fig 13-4, 13-5)

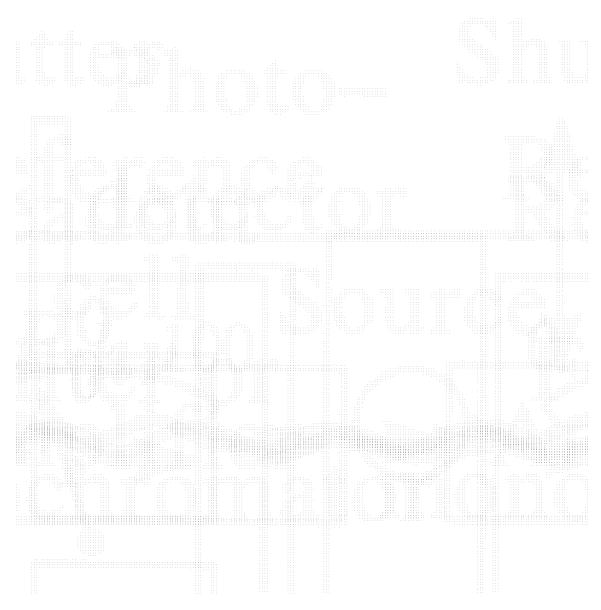

### **Typical UV-Vis Spectrophotometers:**

(Fig 13-12)

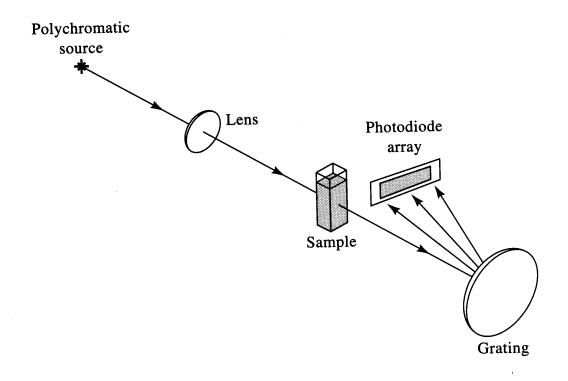

includes  $\lambda$  selection

(a) single beam (SB) (b) double-beam (DB)-in-space (c) double-beam-in-time

### **Multichannel Spectrophotometer**

No monochromator, but disperses transmitted light and measures "all wavelengths at once" (Fig 13-13)

No scanning - simple and fast

More expensive

Limited resolution

#### Applications of UV-Vis Spectrometry:

$$M + h\nu \xrightarrow{excitation} M^* \xrightarrow{relaxation} M + h\nu / heat$$

How probable?

 $\varepsilon$  ranges 0 to ~100,000 L/mol·cm

"forbidden" "allowed"

electronic transition

Which electrons get excited?

In UV-Vis, photon provides enough energy to move outer valence (bonding) electrons

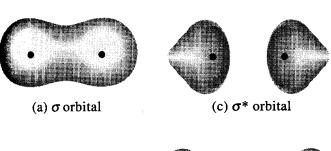

#### Organic molecules

 $\psi_{\sigma} = \psi_{s_A} + \psi_{s_B}$  Bonding  $\sigma$  molecular orbital

 $\psi_{\sigma^*} = \psi_{s_A} - \psi_{s_B}$  Antibonding  $\sigma^*$  molecular orbital

 $\psi_{\pi} = \psi_{p_A} + \psi_{p_B}$  Bonding  $\pi$  molecular orbital

 $\psi_{\pi^*} = \psi_{p_A} - \psi_{p_B}$  Antibonding  $\pi^*$  molecular orbital

(b)  $\pi$  orbital (d)  $\pi$ \* orbital

Fig 14-1

#### $\sigma$ , $\pi$ (bonding) and n (non-bonding) electrons

$$\begin{array}{ccc}
\bullet & & & \circ \\
& & & & \circ \\
& & & & \circ \\
\bullet & & & & \circ
\end{array}$$

$$\begin{array}{cccc}
\bullet & = \sigma \\
\times & = \pi \\
\circ & = n$$

Fig 14-2

#### Arrange in terms of energy:

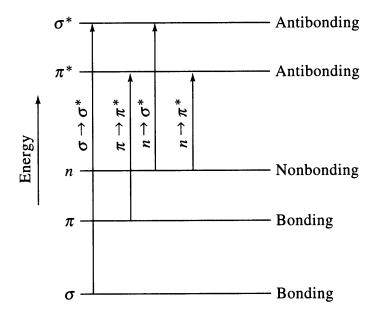

Fig 14-3

 $\pi \rightarrow \pi^* \text{ n} \rightarrow \pi^* \Delta E \text{ small } (\lambda = 200-700 \text{ nm}) \epsilon = 10-10,000 \text{ L/mol·cm}$ 

Ideal for UV-Vis spectrometry of organic chromophore

# • Red shift of $\lambda_{max}$ with increasing conjugation

CH<sub>2</sub>=CHCH<sub>2</sub>CH<sub>2</sub>CH=CH<sub>2</sub> 
$$\lambda_{max}$$
 =185 nm  
CH<sub>2</sub>=CHCH=CH<sub>2</sub>  $\lambda_{max}$  =217 nm

• Red shift of  $\lambda_{max}$  with # of rings

Benzene 
$$\lambda_{max} = 204 \text{ nm}$$

Naphthalene  $\lambda_{max} = 286 \text{ nm}$ 

• Blurred with **solvent** 

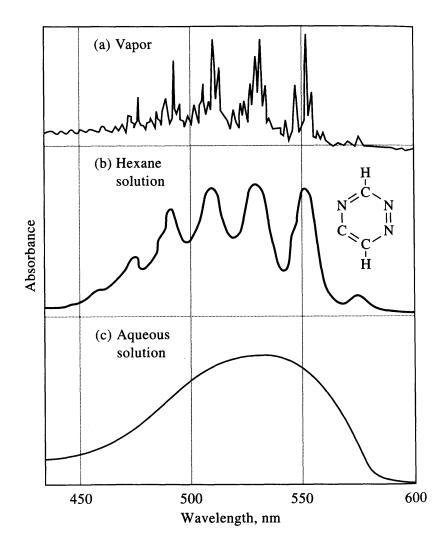

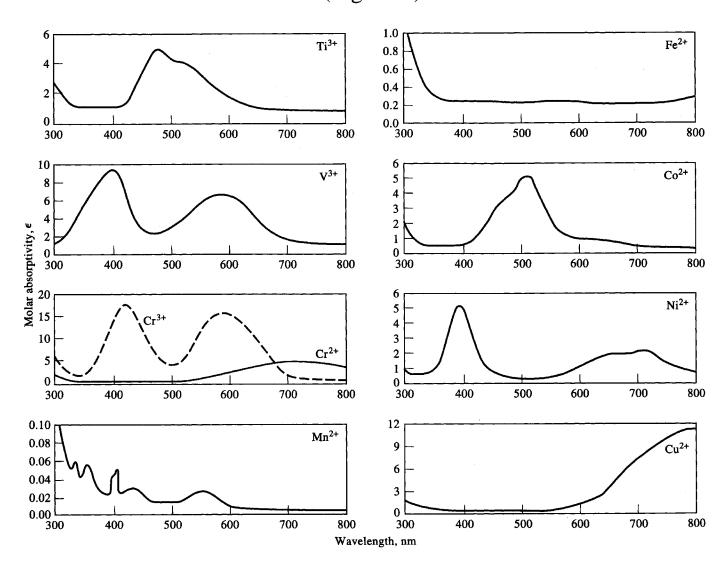

Fig 14-5

### **Inorganic Ions**

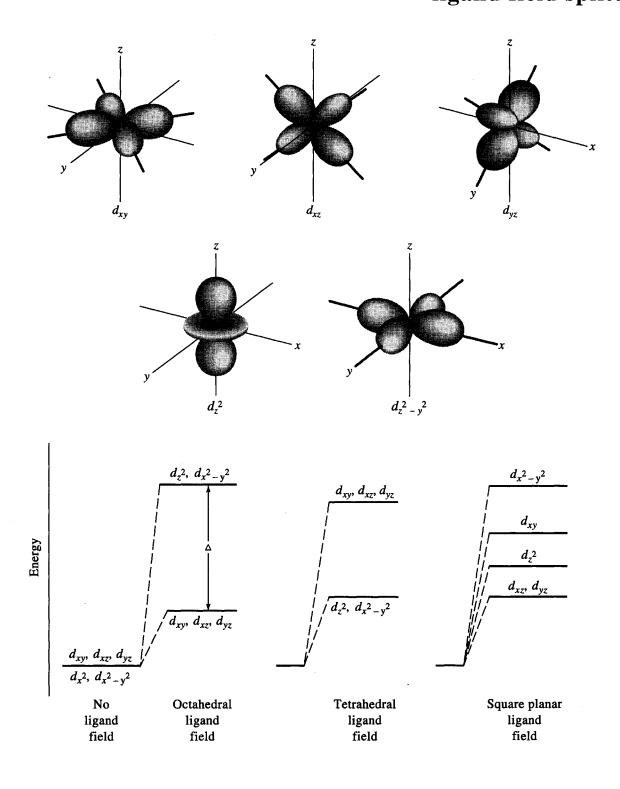

Most transition metal ions are colored (absorb in UV-vis) due to d→d electronic transitions (Fig 14-7)

#### Remember:

- Solution absorbs red appears blue-green
- Solution absorbs blue-green appears red

# Ligands cause different interactions with d electrons (Fig 14-8, 14-9) - ligand field splitting

## Ligand Field Strengths:

	$\lambda_{max}$ for complex (nm)				
	Increasing Ligand Field Strength →				
	6Cl-	6H <sub>2</sub> 0	6NH <sub>3</sub>	3en	6CN-
Cr(III)	736	573	462	456	380

$$I\text{-} 
$$vis \qquad \qquad UV$$$$

"Spectrochemical Series"

#### **Solvent Effects:**

(i) Solvent transparency in UV (Table 14-6)

Solvent	Approximate <sup>a</sup> Transparency Minimum (nm)		
Water	190		
Ethanol	210		
n-Hexane	195		
Cyclohexane	210		
Benzene	280		
Diethyl ether	210		
Acetone	330		
1,4-Dioxane	220		

<sup>&</sup>lt;sup>a</sup>For 1-cm cells.

- (ii) Polar solvents "blur" vibrational features more than nonpolar
- (iii) Polar solvents more likely to shift absorption maxima Shifts of  $\lambda_{max}$  with solvent polarity

 $n \rightarrow \pi^*$  hypsochromic/blue shift

 $\pi \rightarrow \pi^*$  bathochromic/red shift

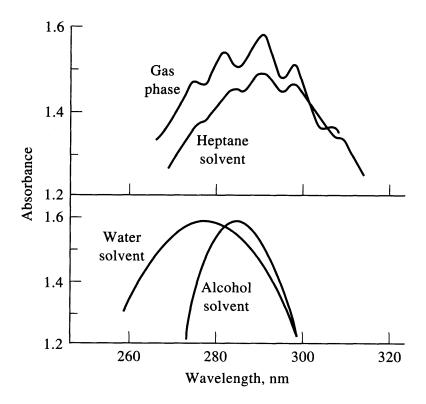

Fig 14-12

Solvent effects mean UV-Vis not reliable for qualitative but excellent for quatitative analysis.
